

Limit Overrun Race Condition Leading to Business Logic Bypass

Summary

During a security assessment, I identified a race condition vulnerability that allowed application-enforced limits to be bypassed through concurrent request processing. The application validated requests independently before updating its internal state, creating a timing window where multiple requests could successfully pass validation simultaneously.

By exploiting this synchronization flaw, it was possible to exceed intended operational limits and perform actions beyond the application's business restrictions.

Technical Details

The application relied on a check-before-update workflow to determine whether a request should be accepted. However, this validation was not performed as an atomic operation.

When several identical requests were sent concurrently, each request evaluated the same resource state before any updates were committed. Since all requests observed identical conditions, they were accepted and processed successfully.

This behavior created a race window that allowed multiple operations to complete before the application enforced its intended limit.

Simplified Flow

1. The application verifies whether an operation is permitted.
 2. Multiple identical requests are transmitted simultaneously.
 3. Every request passes the validation check.
 4. The application processes all accepted requests.
 5. Internal state is updated after processing.
 6. The configured limit is exceeded due to concurrent execution.
-

Impact

Successful exploitation could allow an attacker to:

- Bypass application-enforced usage limits.

- Execute duplicate or repeated privileged operations.
 - Abuse business logic restrictions.
 - Create inconsistent application or database states.
 - Consume resources beyond intended limits.
 - Trigger unintended financial or operational consequences.
 - Gain an unfair advantage over legitimate users.
-

Risk Assessment

Severity: High

Applications that process critical business operations without proper synchronization are vulnerable to race condition attacks. Depending on the affected functionality, exploitation may result in financial loss, inventory inconsistencies, duplicated transactions, unauthorized resource consumption, or disruption of normal business operations.

Root Cause

The vulnerability exists because request validation and state modification are performed as separate operations without adequate synchronization.

The application does not ensure atomic execution, allowing multiple concurrent requests to validate against the same pre-update state before any request commits its changes. This timing issue enables multiple requests to succeed when only one should be permitted.

Recommended Remediation

- Implement atomic server-side operations for critical workflows.
 - Use database transactions with appropriate isolation levels.
 - Apply locking mechanisms where shared resources are modified.
 - Revalidate application state immediately before committing changes.
 - Introduce idempotency keys for sensitive or repeatable operations.
 - Queue or serialize requests that modify critical business data.
 - Monitor and rate-limit bursts of concurrent requests targeting sensitive endpoints.
-

Security Lessons

Race condition vulnerabilities are often difficult to detect because individual requests appear to behave correctly during normal testing. Effective security assessments should include concurrency testing to identify timing-related flaws that may bypass business logic.

Critical operations involving balances, quotas, inventory, discounts, coupons, payments, or account state should always be implemented as atomic transactions to prevent concurrent request exploitation and maintain data integrity.

The screenshot shows the Burp Suite interface. The top bar indicates the target is `https://0a0f00030396d7298028b2af00990006.web-security-academy.net`. The left pane shows the 'Request' tab with a POST request to `/cart/coupon`. The request body contains a CSRF token and a coupon code: `&csrf=YcysLlc50L3lC2vmYQ9LfKUNUXKulfoa&coupon=PROMO20`. The right pane shows the 'Response' tab with a 200 OK status and the message 'Coupon applied'. Red arrows point from the coupon code in the request body to the 'PROMO20' code in the application's checkout message.

Request:

```
POST /cart/coupon HTTP/2
Host: 0a0f00030396d7298028b2af00990006.web-security-academy.net

Coupon applied
```

For 20% off use code at checkout **PROMO20**

The screenshot shows a web application interface. At the top right, there are links for 'Home' and 'My account', and a shopping cart icon with '0' items. Below this, the 'Store credit' is shown as '\$34.60'. The main message is 'Your order is on its way!'. Below this is a table with the following items:

Name	Price	Quantity
Lightweight "I33" Leather Jacket	\$1337.00	1

At the bottom, the 'Total' is shown as '\$15.40'. Red arrows point from the 'PROMO20' code in the previous screenshot to the 'Total' and the 'Lightweight "I33" Leather Jacket' item.
